Contents

1. Comparison Operators
2. Conditional Statements
3. Rounding and Formatting
4. Debugging
5. Complex Conditional Statements
6. Variable Lifespan
7. Logical Operators: **and, or, not**

Comparison Operators

Comparison Operators

Operator	Notation	Used for
Equality	$==$	numbers, dates, other comparable types
Difference	$!=$	
Bigger	$>$	
Bigger or equal	\geq	
Less	$<$	
Less or equal	\leq	

Comparing Values

- In programming, we can compare values
- The result of logical expressions is value: **True** or **False**

```
a = 5
b = 10
print(a < b)           # True
print(a > 0)           # True
print(a > 100)          # False
print(a < a)            # False
print(a <= 5)           # True
print(b == 2 * a)        # True
```

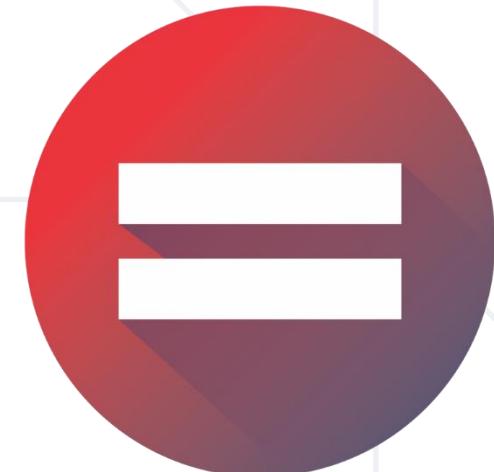

Comparing Values

- Comparing text using equality operator (`==`)

```
a = 'Example'  
b = a  
print(a == b)      # True
```

```
a = input()  
b = input()  
print(a == b)      # True
```

Entering the same
value

Boolean Variable

- Has only the following two values: **True** or **False**

```
is_valid = True
```

- Can also be created with a condition that evaluates to true or false

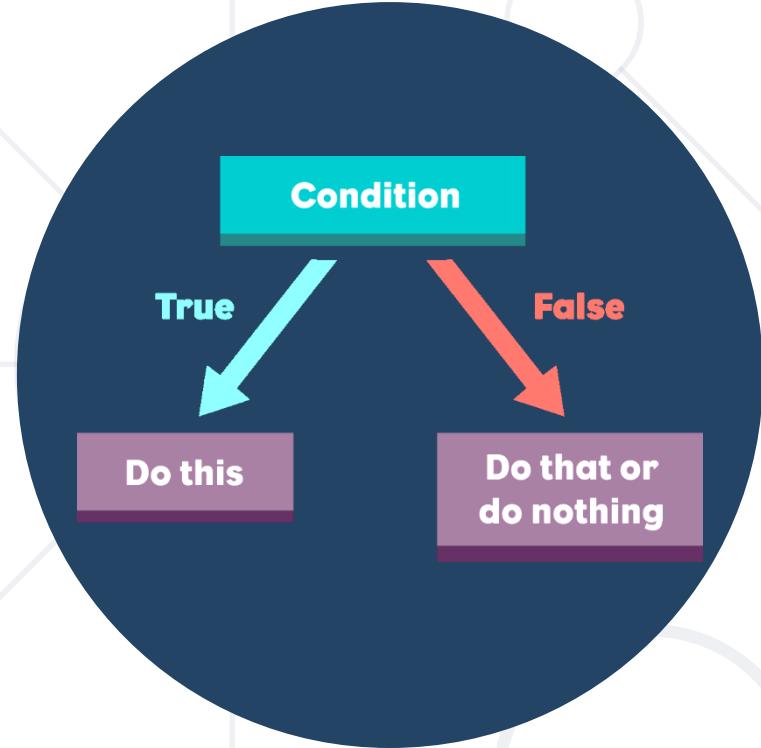

```
is_positive = a > 0
```

Boolean Variable - Example

```
a = 5
is_positive = a > 0
print(is_positive) # True
```

```
a = -5
is_positive = a > 0
print(is_positive) # False
```

Conditional Statements

Simple Conditional Statement

- We often check conditions and perform actions based on a result

```
if ....:  
    # Code to execute
```

Condition
(boolean expression)

Code to execute if the
condition is true

- The result is **True** or **False**

Conditional Statement: if-else

- In case of **false condition**, we can perform other actions – through the **else** construction

```
if ...:  
    # code to be executed  
else:  
    # code to be executed
```

Code to be executed when
the condition is false

Block of Code

- Tabs form **block of code** (a group of commands)
 - The line that **matches** the condition is executed

```
color = 'red'  
if color == 'red':  
    print('Red')  
else:  
    print('Yellow')  
print('bye')
```

Block of Code

- Without tabs, the **last** line will also be executed

```
color = 'red'  
if color == 'red':  
    print('Red')  
else:  
    print('Yellow')  
print('bye')
```

The lines that match the condition are executed

It is always executed – not part of the if / else construction

```
C:\users\...  
Red  
bye  
  
Process finished with exit code 0
```

Rounding and Formatting

Working with Numbers

- In programming, we can round real numbers

- Rounding up to the next (bigger) integer:

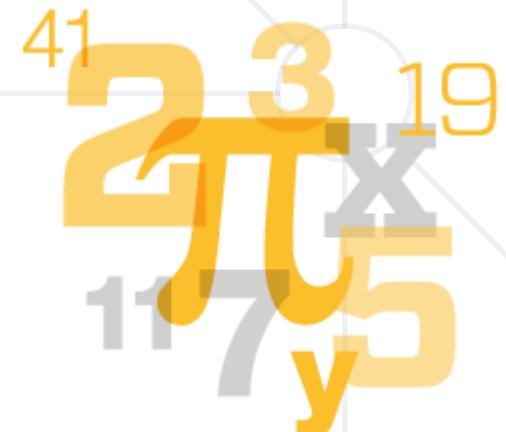

```
up = math.ceil(23.45) # 24
```

- Rounding down to the previous (smaller) integer:

```
down = math.floor(45.67) # 45
```

- Finding the absolute value

```
example1 = abs(-50) # 50  
example2 = abs(50) # 50
```

Rounding and Formatting

- Rounding to 2 decimal places:

```
rounded = round(45.67852, 2) # 45.68
```

- Formatting to 2 decimal places:

```
print(f"123.456:.2f") # 123.46
```

Number of characters after
the decimal point

- Difference between formatting and rounding

```
print(round(45.6000, 4)) # 45.6  
print(f"45.6000:.4f") # 45.6000
```

Debugging

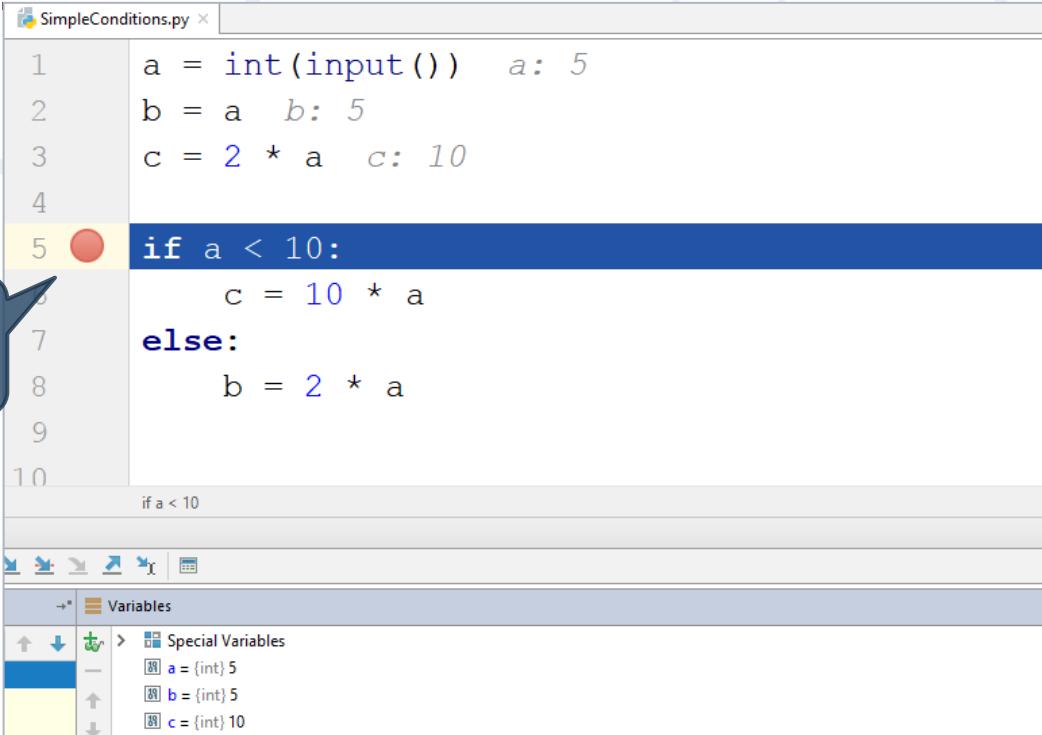

Simple Operations with Debugger

Debugging

- Process of tracing the execution of the program
 - Allows us to detect errors (bugs)

Breakpoint

The screenshot shows a Python debugger interface with the file `SimpleConditions.py` open. The code contains the following:

```
1 a = int(input()) a: 5
2 b = a b: 5
3 c = 2 * a c: 10
4
5 if a < 10:
6     c = 10 * a
7 else:
8     b = 2 * a
9
10 if a < 10
```

A red circular breakpoint marker is positioned at the start of the `if` statement on line 5. The variable pane at the bottom shows:

Variables
a = {int} 5
b = {int} 5
c = {int} 10

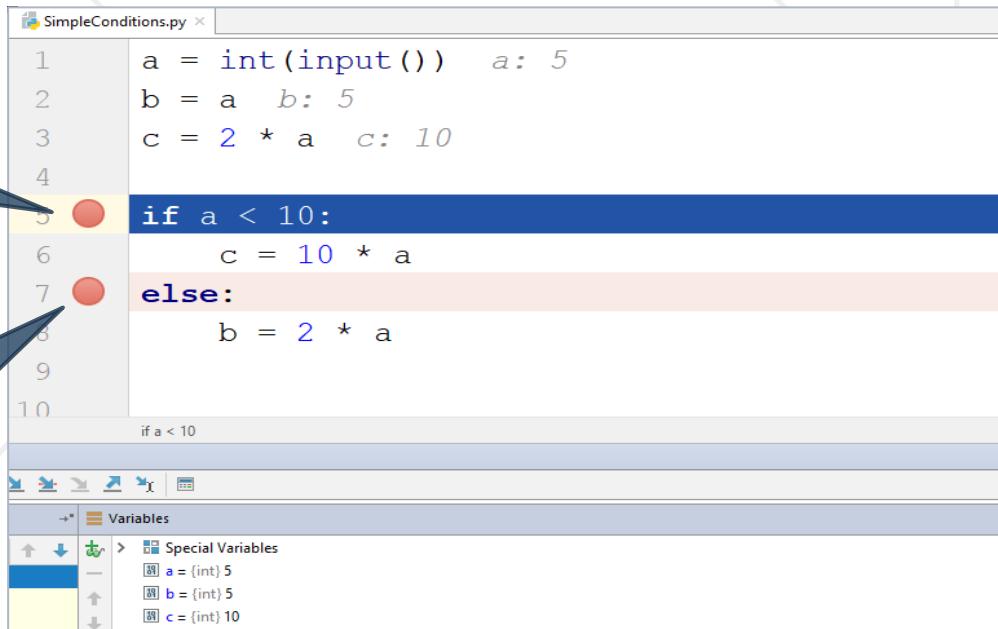

Debugging in PyCharm

- Pressing **[Shift + F9]** will start the program in debug mode
- We can move to the next step with **[F8]**
- We can create **[Ctrl + F8]** breakpoints
 - We can directly reach them using **[F9]**

Breakpoint

Breakpoint

The screenshot shows the PyCharm IDE interface. In the code editor, there is a Python script named `SimpleConditions.py`. The code contains the following:

```
1 a = int(input()) a: 5
2 b = a b: 5
3 c = 2 * a c: 10
4
5 if a < 10:
6     c = 10 * a
7 else:
8     b = 2 * a
9
10 if a < 10
```

Two red circular markers, representing breakpoints, are placed on the first two lines of the `if` block. A blue callout bubble labeled "Breakpoint" points to the marker on line 5. Another blue callout bubble labeled "Breakpoint" points to the marker on line 7. At the bottom of the screen, the PyCharm toolbar is visible, along with the "Variables" tool window which displays the current values of variables `a`, `b`, and `c`.

Complex Conditional Statements

Series of Checks

- The construction `if/else` - `if/else...` is series of checks

```
if ....:  
    # code  
elif ....:  
    # code  
elif ....:  
    # code  
else:  
    # code
```

TRUE OR FALSE?

- When the condition is true, the evaluation of the next conditions is **not continued**

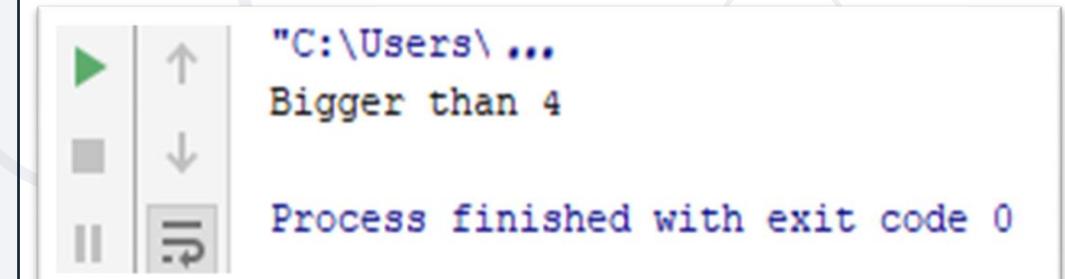

Series of Checks - Example

- The program checks the first condition, determines that it is true and ends

```
a = 7
if a > 4:
    print('Bigger than 4')
elif a > 5:
    print('Bigger than 5')
else:
    print('Equal to 7')
```

Only 'Bigger than 4' is displayed

```
C:\Users\ ...
Bigger than 4

Process finished with exit code 0
```

Variable Lifespan

Scope of Usage

Variable Lifespan

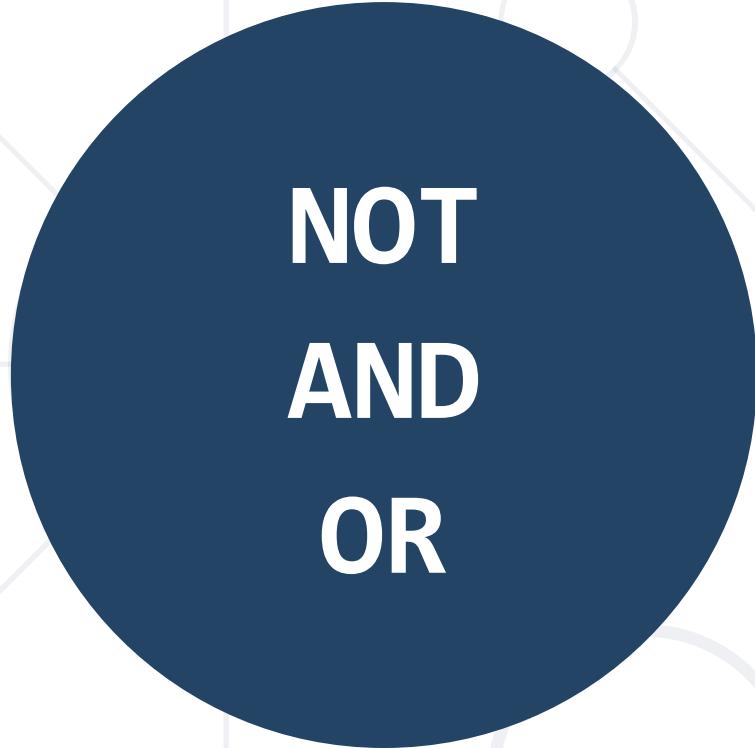

- Example: The variable **salary** will exist **only** if it is initialized somewhere in the program

```
current_day = "Monday"  
if current_day == "Monday":  
    salary = 1000  
print(salary) # 1000
```

Variable Lifespan

- Example: The variable **salary** will **not** exist if it is not initialized somewhere in the program

```
current_day = "Tuesday"  
  
if current_day == "Monday":  
    salary = 1000  
  
print(salary) # Error
```

NOT
AND
OR

Logical Operators

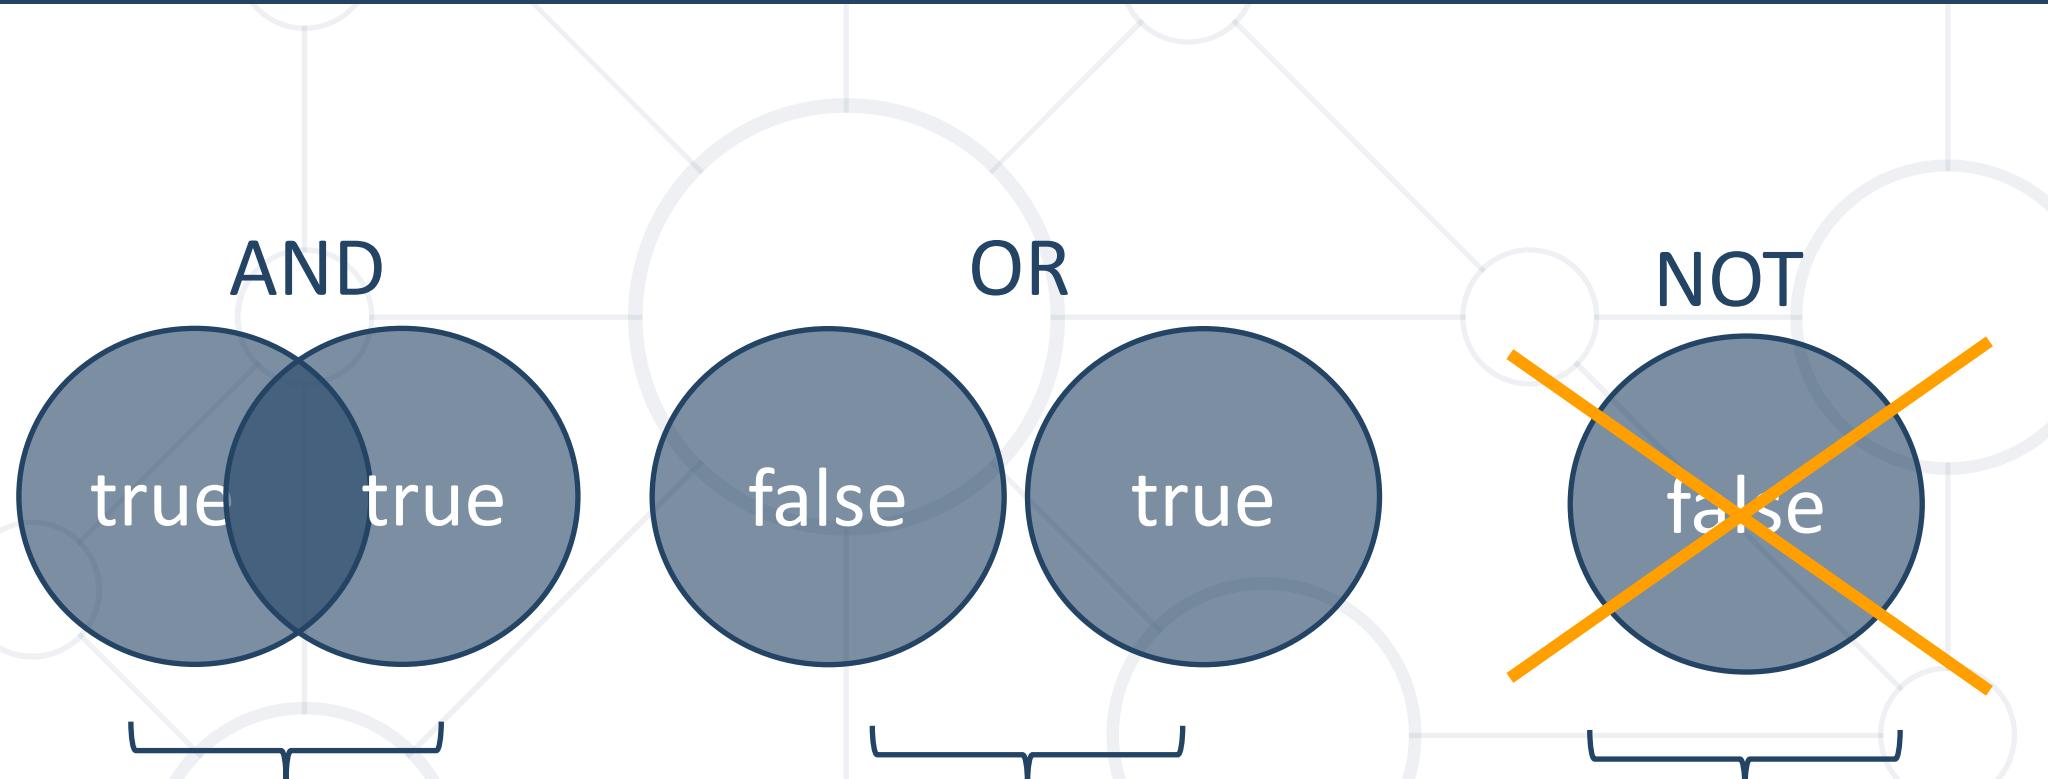

Checking Complex Conditions

Logical Operators

- Logical checks are based on **logical conditions**
- The **logical operators** in Python are:
 - Logical **AND**
 - Logical **OR**
 - Logical **NOT**
- **Brackets ()** change the order

Logical Operators: Explanation

**Both conditions
must be true**

**One condition
must be true**

NOT

Logical AND

- Returns the Boolean value **true** if all of the operands are **true** and **false** otherwise
- Example: check **number** is in the following **range** [100; 200]

```
if number >= 100 and number <= 200:  
    print("Number is in range")
```

Logical OR

- The result of the expression is **true** if one of the operands is **true**, otherwise the result is **false**

```
product == "tea" or product == "water"
```

- Problem: **check for food or drink**
 - Read single line and print "**drink**", "**food**" or "**unknown**"
 - Foods: **curry, noodles, sushi, spaghetti**
 - Drinks: **tea, water, coffee**
 - Everything else is **unknown**

Logical NOT

- Logical negation returns **true** when the operand is **false**, and **false** when the operand is **true**
- Example: **check for valid number**
 - A number is **valid** if is in the range [100...200] or is equal to 0

```
isValid = (num >= 100 and num <= 200) or num == 0:  
  
if not isValid:  
  
    print("invalid")
```

Summary

- Comparison operators
- Condition statements
- Rounding and Formatting
- Series of checks
- Debugging
- Variable Lifespan
- Logical Operators
